Development of a Hybrid Actuation System for Haptic Interfaces

Carlos Rossa

University of Paris VI & French Atomic Energy Commission

January 15th 2014

A B + A B +

Schematic representation of a haptic interaction

• Ideal haptic interface :

$$\frac{Z_{perçue}}{Z_h} = 1$$

- Free motion $(Z_h \rightarrow 0)$: no inertia and no friction
- Virtual obstacle $(Z_h \rightarrow \infty)$: infinite output impedance

Actives Interfaces

Schematic representation of a haptic interaction

Advantages

- Allow for energy dissipation and restitution
- Low response time
- Relatively good control performance

Drawbacks

- Low torque per volume unit
- Need reduction stages
- Low efficiency

Stability criteria Limitation of gains Experimental results

Control premise

Only two input variables :

- The desired torque
- The measured position

Elements to be taken into account :

The maximal gain for the motor is :

$$K_{lim} < \frac{2b}{T}$$

- Sollow a reference torque using the motor/brake
- Active torque Γ_{sat} 0.2 Nm
- Passive torque 5.3 Nm

★ ∃ ► < ∃ ►</p>

Stability criteria Limitation of gains Experimental results

Limitation of the motor's stiffness

The desired stiffness K_h is :

$$K_{h(k)} = \frac{\Gamma_{h(k)} - \Gamma_{sb(k-1)}}{\delta\theta}$$

• Γ_h reference torque, Γ_{sb} motor's torque, $\delta\theta$ position variation

The torque imposed by motor is :

If K_h is inferior to K_{lim}

$$\Gamma_{sb(k)} = \Gamma_{h(k)}$$

3 Otherwise $K_h > K_{lim}$; thus :

$$\Gamma_{sb(k)} = K_{lim}.\delta\theta + \Gamma_{sb(k-1)}$$

Inertia	134	101k	279	418	gcm ²
Viscous fric	5.24	144	567	732	μ Nms
Min torque	4.16	114.4	25.8	30	mNm
Torque/vol	2.24	-	48.1	17.75	kN/m^2

Less friction up to 22.7 rev/s

4 ∃ > < ∃ >

Experimental setup Results

Sommaire

1 Unidirectional brake approach

2 Magnetorheological brakes design

Integrated actuator design

4 Hybrid actuator control

Experimental setup Results

Torque and stiffness asymmetry

Simulation of an angular spring

- Asymmetry due to the stiffness K_{lim} limitation
- Asymmetry due to the torque Γ_{sat} limitation

4 A 1

4 ∃ > < ∃ >

Experimental setup Results

Methods

The motor is linked to a 7 :1 capstan transmission (max 1.2 Nm)

- 11 asymmetry levels
- 2 stiffness levels
- 2 maximal displacement $~~15^\circ$ et 30°
- 0%, 10%... 100% 4.5 et 2.9 Nm/rad 15° et 30°

(4 environments)x(11 levels)x(10 times)x(8+9 subjects) = 7480

Conclusions

イロト イボト イヨト イヨト

Conclusions

Design

Magnetostatic model for MR brakes Evaluation and comparison of different geometries

Control

Controller independent of the VE Allows for the application of the actuator in existent devices

Industrial transfer

Perspectives

Conception et commande

Prise en compte des frottements sec et visqueux Compensation de l'hystérésis magnétique/asservissement en champ

Miniaturisation

Détection de couple par mesure de l'impédance électrique Intégration d'un système de mesure de position

Interfaces multi-degrés de liberté

Maximisation de l'espace de travail des freins Actionneur redondants

Contrôle sur l'énergie d'intéraction

L'observateur d'énergie est dénifit par :

$$E(n) = T \sum_{k=1}^{n} \left[\Gamma_{sb} + \Gamma_{b}^{**} \right] \dot{\theta}(k)$$

Redéfinition de S(u)

• Tant que l'énergie observée est positive :

$$S(u) = \beta(u)$$

• Tant que l'énergie d'intéraction est négative :

$$S(u) = 0$$

L'énergie injectée par l'échantillonnage est dissipée par le frein.

.

Flux de puissance

Le frein peut être désactivé si la vitesse et le couple ont le même signe.

- S(u) Taux de participation du moteur
- $\Lambda(u)$ Taux non saturation de l'actionneur

- Dissipation d'énergie : Frein + moteur
- Restitution d'énergie : Moteur

4 ∃ > < ∃ >

Réponse électromagnétique

• Réponse fréquentielle de la bobine

- La fréquence de coupure est de 18 Hz
- Suffisante pour les IHM ?

Réponse électromécanique

- Réponse à un échelon de tension en bouble ouverte
 - Temps de réponse 200 ms

- Réponse à un échelon de courant avec contrôleur PI
 - Temps de réponse 30 ms
